📌 MINI EXEMPLAR

⚠️ *These are NOT full answers. They only show how to begin each section. Students must expand them in the exam.*

Introduction

This test strategy explains how the system will be tested to ensure it meets the client's requirements, functions reliably, and provides a suitable user experience. It outlines the test types, the order of testing, and key dependencies.

Components & Interrelationships

The system is made up of several connected components. Some components rely on shared services, while others depend on earlier steps in the user journey. Because of these links, certain components must be tested before others.

Test Approach

Black-box testing will be used to check user-visible behaviour, white-box testing will verify internal logic and data handling, and integration testing will confirm components operate correctly together.

Order of Testing

Testing will begin with foundational components, then move to individual features, and finish with integrated workflows. This order reflects dependencies identified during system decomposition.

Table Row (starter example)

Date	Component	Test Type	Prerequisites & Dependencies

14/06/2026	User Login	White-box → Black-box → Integration	Requires user accounts, database connection, and session handling.

Date of test	Component to be tested	Type of test to be carried out	Prerequisites and dependencies
17/03/2025	Navigation bar	White box -> Black box -> Integration testing	Navigation bar code must have all the links to pages within and when user clicks on a page on the bar it should take them to the page. Must also be on all pages across site
17/03/2025	Footer	White box -> Black box -> Integration testing	Footer code must have all the links to pages within and when user clicks on a page on the footer it should take them to the page. Must also be on all pages across site
17/03/2025	Account registration	Integration testing	Back-end must be available to store & validate user's detail
17/03/2025	Account registration	Black box -> White box	User's inputted details must be required first before sending to back-end for processing.

(Students should write several rows following this pattern.)

Stakeholder Involvement

Stakeholders will be consulted during user or acceptance testing to ensure the system meets expectations and is practical for real use.

Lifecycle Testing

Testing will be carried out throughout the development lifecycle, beginning with early validation checks and continuing through integration and deployment.

Late-Stage Changes & Regression

If updates are made late in development, targeted tests will focus on the affected components followed by regression testing to ensure no other parts of the system are impacted.

Final Summary

This strategy provides a structured and thorough approach to testing, ensuring that all components are checked appropriately and the system meets its intended purpose.
